

This section introduces the first text table.

The table summarizes key descriptive items.

Each entry uses concise text for easy reading.

Item	Description
Overview	Brief text explaining the main purpose.
Details	Supporting text with additional context.
Notes	Short remarks for quick reference.

This section introduces the second text table.

The table provides another set of text entries.

Category	Text Content
Point One	Short text describing the first point.
Point Two	Short text describing the second point.
Point Three	Short text describing the third point.

he journal shows that the root user was already investigating port 44999 from /root/inv. But the binary journal for the older machine (machine name: layout-aware-ai-services-testing-ramzy, which was active on Apr 28) was inspected for port 44999. This suggests the service was running on a different machine (the previous one - layout-aware-ai-services-testing-ramzy).

Let me look at the binary journal from the previous machine boot. There's a journal file at /var/log/journal/9bbfb952bfad40e9ae2cc44135a3679c/system.journal - this is what root searched.

Since this is GCP and the machine name changed from layout-aware-ai-services-testing-ramzy to layout-aware-testing-tmp, these are likely different VMs or the same instance that was renamed. Port 44999 appears to have been active on the earlier VM. I should dig deeper into the binary journal and older log files to trace where the service actually ran.
